i960® COMPETITIVE BENCHMARK REPORT

Introduction

This report describes the results of performance benchmarks run on the Intel i960® microprocessors and several competitors in the 32-bit RISC field. The microprocessors covered in this report are:

- Intel 80960SA, 80960SB, 80960KA, 80960KB, 80960CA, 80960CF
- Integrated Device Technology (IDT) 3081, 3051, 3052,3041
- Advanced Micro Devices (AMD) 29205, 29200, 29030
- Motorola 68040

The basis of the comparison is a set of synthetic benchmark programs. This report makes every attempt to 1) use accepted practices in running the benchmarks and 2) provide full and unambiguous disclosure of all factors that significantly affect the results.

Why synthetic benchmarks? It is not our contention that the results of synthetic benchmark programs should be the sole factor in selecting a microprocessor. The best indicator of performance is a customer's own benchmark program or — in the absence of that — one resembling the actual application. Developing a benchmark, however, costs time and money and may not be feasible for all customers. The customer may not have an application program developed when considering microprocessor performance. These constraints cause developers to turn to synthetic benchmarks for an indication of microprocessor performance.

Benchmark data in this report is presented using simple bar charts. The following figure is an example of such bar charts; it shows the relative performance of the present line of i960 microprocessors.

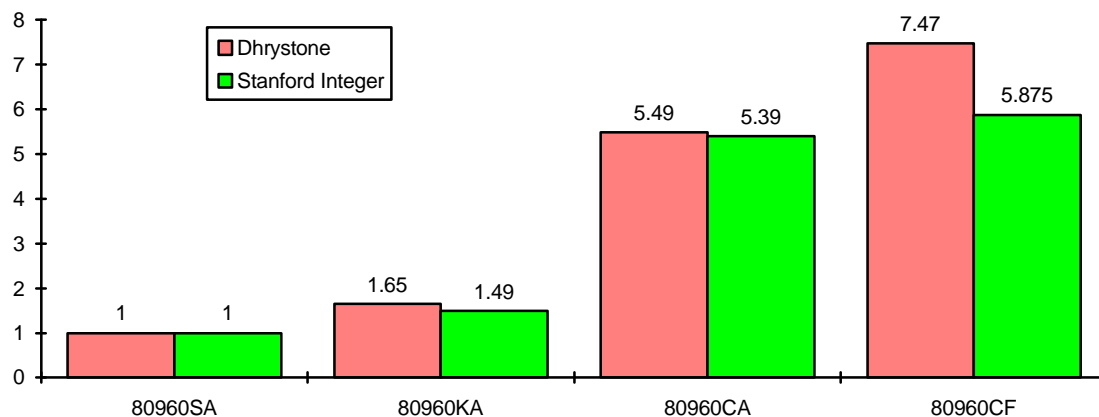

Figure 1. Relative Performance of i960® Microprocessors (not frequency normalized)

In charts comparing an 80960 against one or more competitors we have chosen to display the data as relative to the competitor. In the above chart the 80960CF, 80960CA and 80960KA are shown relative to the 80960SA. Data in these charts is normalized for processor clock frequency unless otherwise noted.

The raw results of each run are presented in tables at the end of this document. These tables contain all data obtained from the benchmarking process. The data in the tables was normalized for frequency and then used to generate the bar charts. The exception to this is the Whetstone test. The Whetstone results were not included in the floating point average. The magnitude of the 80960 Whetstone result may lead one to believe that there is a mistake involved here. There is not. The high value is a result of the aggressive optimization that is possible on some types of program structure with the Intel CTOOLS960 compiler. We chose to leave the Whetstone result out of the floating point average to avoid skewing the graphical results. We chose to leave them in the result table because they were produced with procedures consistent with those set out for this exercise.

This document explores the tradeoffs between various choices of memory subsystem design. The following example shows the differences in performance between more aggressive, costly memory designs and simpler, less costly ones.

Figure 2. Comparison of High- and Low-Cost Memory Systems (KX and CX)

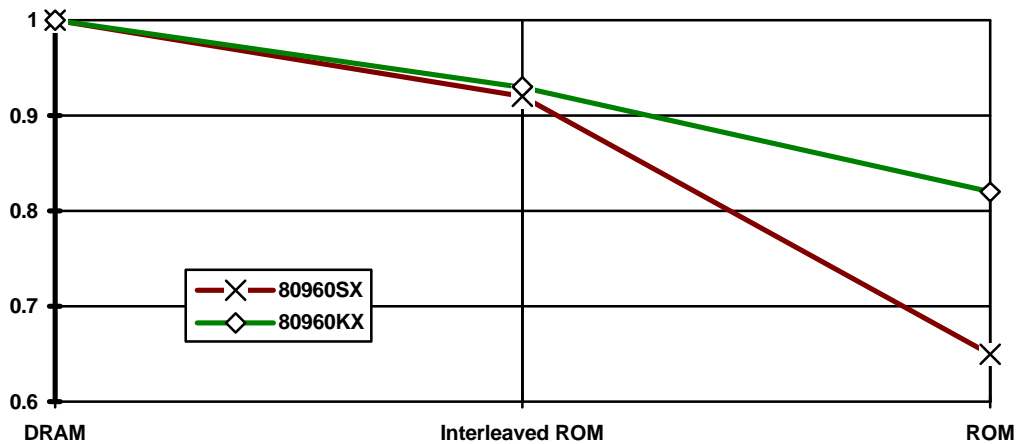

Figure 3. Comparison of high and low memory cost (KX and SX)

The graphs in figures 2 and 3 indicate the averaged results of the Stanford and Dhrystone integer test. Test results were averaged to avoid restricting the result to one type of program structure.

NOTE: the midpoint of the KX line in the second graph is extrapolated from the graph above it. We did not have a waitstate profile for the KX to match the corresponding SX setting.

Selection of programs used in this report was based on general acceptance, well-known behavior and the fact that each is written in the C programming language. Each makes an attempt at a relative measurement of the performance of the microprocessor/compiler combination. Selection was also influenced by the limitations imposed by some of the microprocessor evaluation boards used: some boards did not have adequate memory to support some of the desired programs.

The benchmark programs used include Dhrystone, Whetstone, Stanford integer and floating point sections and the Linpack floating point benchmark. Hardware evaluation platforms were used to generate the data for this report. None of the result data were obtained using software performance simulators.

Methodology

There are few choices in selection of memory technology when designing a microprocessor subsystem. DRAM is the predominant read/write memory technology. ROM, Flash, and EPROM are the predominant technologies for read-only (or read-mostly) memory subsystems. SRAM subsystems are expensive beyond practicality, as code and data size of applications continues to grow beyond the 1 Mbyte limit.

The system designer must work within the bounds of these available memory technologies. For example, if a system designer must use 80 ns DRAM technology, the relevant question of performance is — How fast can the microprocessor execute from 80 ns DRAM?

A 32-bit microprocessor memory subsystem typically resembles one of the three subsystems described in Table 1.

Table 1. Typical 32-Bit Microprocessor Memory Systems

| Cost | Performance | Code Size | Description |
|----------|------------------|-------------------|---|
| high | high | small to moderate | Code and data are located in fast SRAM. SRAM provides access times on the order of 10 - 35 ns. Not a common design, but simple to implement. Practical for applications which have little code and are not cost-sensitive. |
| moderate | moderate to high | moderate to large | Code and data are located in DRAM. The code and initialized data are loaded from a backplane bus or inexpensive ROM at initialization. Mainstream, inexpensive DRAM technology typically provides 70 to 80 ns access time and fast page mode access capability. The system designer can trade off interface cost and performance using different degrees of complexity such as burst mode support and interleaving. Performance may also be enhanced in these systems with a small, fast SRAM memory dedicated to frequently accessed data. |
| low | low to moderate | large | Code is executed from ROM. Data is located in DRAM. The system designer can increase performance by interleaving the ROM subsystem. Since this design is driven by low cost, the DRAM subsystem is typically implemented at the lowest possible cost. |

Microprocessor performance is influenced by several elements; categorized below as either *intrinsic* or *extrinsic*:

- *Intrinsic* elements generally are not or cannot be varied for performance analysis purposes. These properties are inherent to the microprocessor:
 - Architecture and internal implementation (e.g. cache size, instruction set, registers)
 - Efficiency of the external memory interface (e.g. instruction fetch bandwidth)
 - Compiler efficiency (assuming that the best compiler is selected with the highest optimization turned on)
- *Extrinsic* elements can be varied depending on application requirements, performance and cost constraints:
 - Clock speed
 - Bus bandwidth (memory wait states)

Since many factors influence microprocessor performance, it is necessary to choose an equitable reference or baseline for a fair performance comparison. For this performance report, *memory technology* and clock speed have been chosen as the common reference for measuring performance of industry standard benchmarks.

We have chosen to equalize these key factors to make them common to all the comparison cases considered here.

- To equalize the clock rate factor, results of units with higher clock rates were scaled downward to reflect the lower clock rate. The highest rate in the group was the 33 MHz used on the Intel TomCA board. The lowest was 16 MHz shared by the AMD29200, AMD29205 and the Intel EV80960SX boards.
- To equalize memory subsystem performance, the competitors' memory speed were considered on a case by case basis and the wait state profile of the corresponding Intel board was adjusted to emulate memory devices of equal speed.

Each processor's external bus interface is different; consequently, the logic used to implement the DRAM interface for each processor is also different. The relative complexity of the support logic required to implement a particular DRAM interface is significant to the system designer for consideration of system cost and engineering resources required for design and validation.

The competitors' evaluation hardware are designed with DRAM. The memory wait state profiles for this hardware cannot be altered, but are optimized for a particular subsystem complexity as follows:

- DRAM: 80 ns non-interleaved
- DRAM: 80 ns interleaved, CAS interleaving for reads only, no write posting
- DRAM: 80 ns interleaved, CAS and RAS interleaving

Benchmark Programs

Table 2. Benchmark Program Descriptions

| Program | Description | Units of Measure |
|-----------|--|---|
| Dhrystone | Tests integer performance. String manipulation is a common action in this program. The version used here is 2.1. | Dhrystones/Second |
| Whetstone | Tests floating point performance. | Millions of Whetstones/Second |
| Stanford | Contains both integer and floating point sections. Uses a suite of well-known problems such as the towers of Hanoi and sorting algorithms. | Stanford integer composite; Stanford floating point composite (Smaller is better) |
| Linpack | Measures floating point performance using matrix manipulation. | Thousands of FLOPS/Second |

Benchmark Environment

Development Software/Workstation

All test code was generated in a cross-development environment. None of the test programs were compiled on the machine on which they ran. Program generation was done on two machines.

All test programs for non-Intel targets were compiled on a Dell 450DE, 80486 machine running at 50 MHz. All software tools for the AMD, IDT and Motorola microprocessors are DOS based. Compile times were not documented; this was not the goal of this report. Care was taken to ensure that the compilers used were the latest revision.

Intel software tools used in this report are UNIX based. The 80960 applications department's benchmarking environment includes an 80386-based UNIX System V machine with several 80960 boards attached.

The manufacturers and versions of software development tools are as shown in Table 3.

Table 3. Software Development Tools

| Manufacturer | Tool Name | Version | Target |
|------------------------------|------------|----------|-----------------------------|
| Metaware | High C 29K | 3.1 | AMD 29030, 29200, 29205 |
| Microtec Research Inc. | MCC68K | 4.21 | Motorola EC68040 |
| Integrated Device Technology | IDT/c | 4.1 | 3051,3052,3081,3051 |
| Intel | CTOOLS960 | X4.0.324 | 80960SA, SB, KA, KB, CA, CF |

All compilers used offer various levels of optimization. Runs were conducted at each of two optimization levels - default and maximum - to demonstrate the improvements offered by each tool's optimization efforts. All charts are based upon maximally optimized code. Maximum optimization is based on the recommendation of the compiler literature.

Target Hardware

Table 4 shows the hardware configurations and memory used to conduct these benchmarks.

Table 4. Hardware Configuration and Memory

| CPU / Eval Board | Clocking | Memory Speed | Memory Description |
|--|---|------------------|--|
| Intel 80960SA/SB EV80960SX (Standalone, serial connect to host) | 16 MHz (CPU); 16MHz (Bus) | 100ns paged DRAM | 2-way interleaved DRAM, CAS and RAS interleaving for reads only - no write posting Variable through the use of an added PC board. See comparative sections for a description of profiles. |
| Intel 80960 KA/KB QT960 (Standalone, serial connect to host) | 20 MHz (CPU) 20 MHz (Bus) | 15 ns SRAM | Programmatic control of wait state timing. Three profiles were used. See comparative sections for a description of profiles. |
| Intel 80960CA/CF TomCAt (Standalone, serial connect to host) | 33 MHz (CPU) 33 MHz (Bus) | 15 ns page SRAM | Programmatic control of waitstate timing. Four profiles were used. See comparative sections for a description of profiles. |
| AMD 29030 EB29030 (ISA bus devel. card) | 25 MHz (CPU) 25 MHz (Bus) | 80 ns paged DRAM | 2-way interleaved DRAM, CAS and RAS interleaving for reads only - no write posting Read cycle - A 3 2 1 D 1 D D D Write cycle - A 3 2 1 D 1 D 1 D 1 |
| AMD 29200: SA29200 (Standalone, serial connect to host) | 16 MHz (CPU) 16 MHz (Bus) | 80ns paged DRAM | 2-way interleaved DRAM, CAS and RAS interleaving for reads only - no write posting Read cycle - A 2 1 D D D D 1 A Write cycle - A 2 1 D 1 D 1 D 1 D 1 A |
| AMD 29205: SA29205 (Standalone, serial connect to host) | 16 MHz (CPU) 16 MHz (Bus) | 80ns paged DRAM | 2-way interleaved DRAM, CAS and RAS interleaving for reads only - no write posting Read cycle - A 2 1 D D D D 1 A Write cycle - A 2 1 D 1 D 1 D 1 D 1 A |
| IDT 3081E, R30051E, R3041* R3052E: 7RS385 (Standalone, serial connect to host) | 25 MHz (CPU) 25 MHz (Bus) * 3041 was run at 20MHz | 80ns paged DRAM | 2-way interleaved DRAM, CAS and RAS interleaving for reads only - no write posting Read cycle - A 2 1 D D D D 1 A Write cycle - A 2 1 D 1 D 1 D 1 D 1 A |
| Motorola EC68040 MVME167 (VME bus card) | 25 MHz (CPU) 25MHz (Bus) | 70ns paged DRAM | 2-way interleaved DRAM, CAS and RAS interleaving for reads only - no write posting Read cycle - A 2 1 D D D D 1 A Write cycle - A 2 1 D 1 D 1 D 1 D 1 A |

Platform Specifics

Memory Interface Configurations

As described above, the Intel boards used in this report were configured to simulate designs that use memory devices of particular performance. Tables 5, 6 and 7 list the configurations used, described by their bus cycles.

Table 5. TomCat (80960CF/CA) Memory Interface Configuration

| | |
|-------------|---|
| SRAM | Read Cycle A D D D D A Write Cycle A D D D D A |
| DRAM | Read Cycle A 2 1 D D D D 1 A Write Cycle A 2 1 D 1 D 1 D 1 D 1 A |
| ROM | Read Cycle A 3 2 1 D 3 2 1 D 3 2 1 D 3 2 1 D A Write Cycle A 3 2 1 D 3 2 1 D 3 2 1 D 3 2 1 D A |

Table 6. QT960 (80960KA/KB) Memory Interface Configuration

Hardware Modifications

The EV80960SX board required the addition of a small PC board containing a PAL and a DIP switch to implement waitstate configurability. This was the only hardware modification performed during this exercise.

Relative Performance of the 80960 Family (not frequency normalized)

Figure 4. Intel i960 CPU Relative Integer Performance (relative to 80960KA)

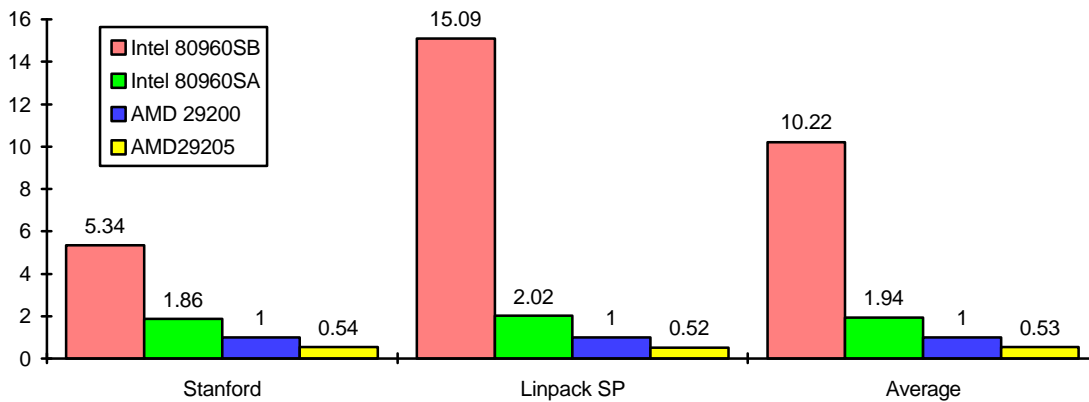

Figure 5. Intel i960 CPU Relative Floating Point Performance (relative to 80960KA)

Intel 80960 Sx vs. AMD 29200/29205

Figure 6. 80960 SX vs. AMD292xx Integer Tests

Figure 7. 80960 SX vs. AMD292xx Floating Point Tests

These tests were conducted with the Intel EVSX board in its DRAM configuration. It should be noted that the AMD evaluation boards used in this test arrived in a configuration that utilized floating point trap handlers located in ROM. This had the effect of making the 29205 appear faster than the 29200 on floating point tests. This is because the 16 bit SA29205 has 16 bit wide ROM while the 32 bit SA29200 has 8 bit wide ROM. Also included with the boards was a floating point trap library and some initialization code to change the trap vectors to point to DRAM. This initialization code was not located in the timed part of any test program.

The 80960SA, AMD29200 and AMD29205 utilize floating point emulation software while the 80960SB utilizes hardware dedicated to floating point operations.

Intel 80960 CA vs. AMD 29030

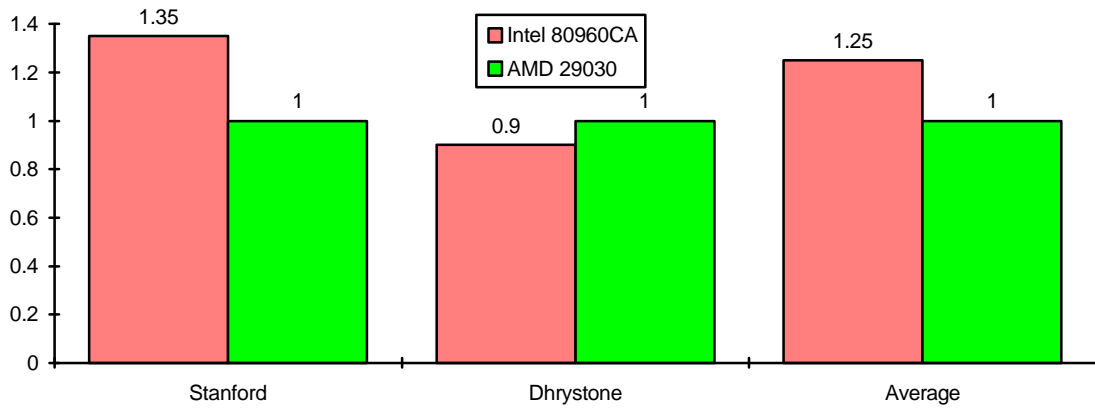

Figure 8. 80960 CA vs AMD 29030 Integer Tests

Figure 9. 80960 CA vs AMD 29030 Floating Point Tests

These tests were conducted with the Intel TomCAat board in its DRAM configuration.

| Whetstone - Single Pr. | 3.18 | 3.01 | 2.88 |
| Whetstone - Double Pr. | 2.98 | 2.82 | 2.65 |
| Stanford Suite - Integer | 345 | 394 | 435 |
| Stanford Suite - FP | 602 | 661 | 712 |
| Linpack - Single Pr. | 648 | 626 | 593 |

Table 15. Intel 80960KB Maximum Optimization

| | SRAM | DRAM | ROM |
|---------------------------------|-------|-------|-------|
| Dhrystone | 19840 | 14847 | 10890 |
| Whetstone - Single Pr. | 7.26 | 7.04 | 6.81 |
| Whetstone - Double Pr. | 5.45 | 5.21 | 4.89 |
| Stanford Suite - Integer | 222 | 258 | 292 |
| Stanford Suite - FP | 377 | 418 | 460 |
| Linpack - Single Pr. | 844 | 833 | 800 |

Note: There are small differences ($\leq 1\%$) between the integer results of the 80960SA/SB and 80960KA/KB. The differences are do to the inclusion of a small amount of floating point code in the non-timed areas of both the Dhrystone and Stanford integer tests. This affects the manner in which code flows through the 512 byte caches of the 80960KA/KB and the 80960SA/SB.

Table 16. Intel 80960CA Default Optimization

| | SRAM | DRAM | ROM |
|---------------------------------|-------|-------|-------|
| Dhrystone | 30283 | 19673 | 11362 |

Table 17. Intel 80960CA Maximum Optimization

| | SRAM | DRAM | ROM |
|---------------------------------|-------|-------|-------|
| Dhrystone | 65562 | 43441 | 31360 |
| Whetstone - Single Pr. | 22.38 | 20.60 | 16.24 |
| Whetstone - Double Pr. | 12.83 | 11.05 | 7.39 |
| Stanford Suite - Integer | 61 | 82 | 94 |
| Stanford Suite - FP | 260 | 304 | 356 |
| Linpack - Single Pr. | 531 | 486 | 405 |

Table 18. Intel 80960CF Default Optimization

| | SRAM | DRAM | ROM |
|---------------------------------|-------|-------|-------|
| Dhrystone | 46253 | 39773 | 31773 |
| Whetstone - Single Pr. | 4.00 | 3.94 | 3.72 |
| Whetstone - Double Pr. | 3.58 | 3.51 | 3.28 |
| Stanford Suite - Integer | 89 | 96 | 99 |
| Stanford Suite - FP | 332 | 344 | 353 |
| Linpack - Single Pr. | 520 | 520 | 518 |

Table 19. Intel 80960CF Maximum Optimization

| | SRAM | DRAM | ROM |
|---------------------------------|-------|-------|-------|
| Dhrystone | 89146 | 77072 | 72333 |
| Whetstone - Single Pr. | 24.09 | 24.08 | 24.06 |
| Whetstone - Double Pr. | 14.18 | 13.72 | 12.09 |
| Stanford Suite - Integer | 56 | 64 | 67 |
| Stanford Suite - FP | 245 | 260 | 268 |
| Linpack - Single Pr. | 570 | 567 | 565 |

Table 20. AMD Results

| AMD 29000 Series¹ | 29030 | 29200 | 29205 |
|-------------------------------------|--------------|--------------|--------------|
| Dhrystone | 34976/36488 | 8939/9604 | 5176/5572 |
| Whetstone - Single Pr. | 1.06/1.06 | .27/.27 | .14/.14 |
| Whetstone - Double Pr. | .75/.75 | .18/.18 | .10/.10 |
| Stanford Suite - Integer | 153/148 | 642/628 | 1129/1097 |
| Stanford Suite - FP | 919/833 | 3467/3058 | 6385/5629 |
| Linpack - Single Pr. | 168/168 | 44/44 | 23/23 |

Table 21. IDT Results

| IDT R3000 Series¹ | 3081E | 3051E | 3041 | 3052E |
|-------------------------------------|--------------|--------------|-------------|--------------|
| Dhrystone | 23574/24096 | 23574/24096 | 10326/10458 | 23574/24096 |
| Whetstone - Single Pr. | 5.26/5.26 | 1.41/1.41 | 0.93/0.93 | 1.51/1.51 |
| Whetstone - Double Pr. | 5.24/5.24 | 1.25/1.25 | 0.88/0.88 | 1.38/1.38 |
| Stanford Suite - Integer | 179/173 | 186/182 | 277/272 | 186/182 |
| Stanford Suite - FP | 248/240 | 493/536 | 845/775 | 492/535 |
| Linpack - Single Pr. | 2656/2656 | 389/389 | 280/280 | 407/407 |

Table 22. Motorola Results

| EC68040¹ | |
|---------------------------------|-------------|
| Dhrystone | 17663/22059 |
| Whetstone - Single Pr. | 4.45/6.95 |
| Whetstone - Double Pr. | 4.45/6.77 |
| Stanford Suite - Integer | 186/114 |
| Stanford Suite - FP | 313/164 |
| Linpack - Single Pr. | 1302/1353 |

¹ In all table cells, the first number is the result of Default optimization; the second is the result of Maximum optimization.
